ABSTRACT

A concise summary of the document

Introduction

This project develops a **Lyrics Similarity Detection Engine** that compares a query song with a catalogue of song lyrics to identify similar passages and detect possible plagiarism. The system reports the most likely matching song(s) along with a similarity score.

System Overview

The engine is implemented in **Python** and preprocesses lyrics by converting text to lowercase, removing punctuation, and tokenizing the content before comparison.

Methodology

The project uses **Knuth-Morris-Pratt (KMP)** for efficient string matching and similarity measures such as **Cosine Similarity** or **Jaccard Similarity** to compare lyrics and calculate similarity scores.

Applications

- Music copyright protection
- Plagiarism detection
- Song originality verification
- Music database analysis

Conclusion

The project provides a fast and effective solution for detecting lyric similarities by combining string matching and text similarity techniques. It helps identify similar songs accurately while reducing manual effort in plagiarism detection.
